Keywords: honey bee, prebiotics, gut microbiota

Introduction

Honey bee (*Apis mellifera*), as an important pollinator, contribute significantly to agricultural productions and the human food supply. Nowadays, bees are stressed by a number of biotic and abiotic factors (pathogens, pesticides, climate change, habitat loss, etc.) which affect health and productivity (Porrini et al., 2016; Alberoni et al., 2016). The European Union ban of antibiotics as feed additives has stimulated the search for natural alternatives. Animals have symbiotic microorganisms, which are important for the proper functioning of gastrointestinal tract (for nutrition and pathogen defence). This link between intestinal microbiota and health status, has encouraged researches to use beneficial gut microorganisms and prebiotics, to improve the health of animals (and humans). Probiotics (mainly lactic acid bacteria) and prebiotics (like inulin) help to protect the intestinal microbial. There are commercial probiotics and/or prebiotics containing diet supplements in beekeeping management too, but most of them have been developed for humans and the differences between the gut microbiota of honey bees and vertebrates may cause an opposite effect (Ptaszyńska et al., 2016). The intestinal system of honey bee contains relatively few bacteria in number and variety. Eight major bacterial groups concentrated in the hindgut: two *Alpha*-, one *Beta*- and two *Gammaproteobacteria*, two closely related *Lactobacillus* group (Firm 4, 5), and one *Bifidobacterium* (Moran, 2015). Some of them are found in all honey bees (*Lactobacilli*, *Beta*- and *Gammaproteobacteria*), but the other groups of bacteria may be completely absent from some animals/individuals (Moran et al., 2012).

Our aim was to investigate the effect of a commercial inulin, as a nutritional supplement, to the composition of gut microbiota of honey bee.

Materials and methods

The control group was fed with one litre sucrose syrup (2 kg sugar in 3 litre water) every second day. Treated groups got the same feed but 30 or 60 g l⁻¹ inulin was added to the syrup. The treatment was performed with three colonies in both cases and the samples (approximately 20-20 worker bees) were collected before the treatment and 2, 4 and 6 weeks later, depending on the duration of the treatment. The intestinal tracts of five bees were isolated, homogenised and diluted in 1% tripton containing saline. Traditional microbiological methods were used to determine the amount of living microbes. We used six different media (Nutrient agar, Compass Enterococcus agar, De Man, Rogosa and Sharpe agar, Eosin Methylene Blue agar, Chromobio Coliform agar and Bifidobacterium medium) to investigate total aerob bacteria, *Lactobacillus*, *Enterococcus*, *Bifidobacterium*, *Escherichia coli* and coliform bacteria.

Results and discussion

We have compared the repeatability of sample processing in case of one and five animals. The complete intestinal system was isolated, homogenised and the colony numbers of bacteria was normalised to one gut. In case of individual isolates, the deviation is very high, especially in case of coliform bacteria (2.0×10^2 - 1.3×10^7) and *Enterococcus* genus. We found that the difference between parallel samples containing five homogenized gut per sample, with the exception of *E. coli* and coliform bacteria, was smaller than for single intestinal samples. Our results show, that the pooling of five intestines gives a more reproducible result. Apart from the differences in the individual animals, the individual honey bee colonies also differed significantly, making the results obtained for several hives incomparable. The literature also confirms that there are very large differences between the intestinal microbes of individual animals in case of honey bee (Moran et al., 2012). Based on our results, two hives were investigated and the exact colony count were not compared, only the tendency of changes due to different treatments was calculated. The bees were treated with sugar syrup and then with increasing inulin concentration, but the effect of the inulin was not detectable. We found that the amount of certain bacteria (total aerob bacteria and *Lactobacillus*) increased significantly (ten to hundredfold) as a result of the sugar syrup treatment. We will carry out further tests to prove our results in spring 2019.

Conclusions

We have developed a method that can be used to test the changes of gut microbiota in honey bee. The prebiotic effect of inulin was not detected by the presently used technique, but we will test more prebiotics in the future.
